## The NASA STI Program Office . . . in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the Lead Center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA's counterpart of peer-reviewed formal professional papers but has less stringent limitations on manuscript length and extent of graphic presentations.
- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or cosponsored by NASA.
- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that complement the STI Program Office's diverse offerings include creating custom thesauri, building customized data bases, organizing and publishing research results . . . even providing videos.

For more information about the NASA STI Program Office, see the following:

## Abstract

The benchmark problems in Category 1 (Internal Propagation) of the third Computational Aeroacoustics (CAA) Workshop sponsored by NASA Glenn Research Center are solved using the space-time conservation element and solution element (CE/SE) method. The first problem addresses the propagation of sound waves through a nearly choked transonic nozzle. The second one concerns shock-sound interaction in a supersonic nozzle. A quasi 1-D CE/SE Euler solver for a nonuniform mesh is developed and employed to solve both problems. Numerical solutions are compared with the analytical solution for both problems. It is demonstrated that the CE/SE method is capable of solving aeroacoustic problems with/without shock waves in a simple way. Furthermore, the simple non-reflecting boundary condition used in the CE/SE method which is not based on the characteristic theory works very well.

## 1. Introduction

The method of space-time conservation element and solution element (abbreviated as the CE/SE method) is an innovative numerical method for solving conservation laws. It is different in both concept and methodology from the well-established traditional methods such as the finite difference, finite volume, finite element and spectral methods. It is designed from a physicist's perspective to overcome several key limitations of the traditional numerical methods.

Simplicity, generality and accuracy are weighted in the development of this method while the fundamental requirements are satisfied by the scheme. Its

salient properties are summarized briefly as follows. First, the concepts of conservation element and solution element are introduced to enforce both local and global flux conservations in space and time instead of in space only. Second, all the dependent variables and their spatial derivatives are considered as individual unknowns to be solved for simultaneously at each grid point. Third, no approximation techniques other than Taylor's series expansion, no monotonicity constraints, and no characteristic-based techniques are used in the design of the scheme. A detailed description of this method and the accompanied analysis can be found in [1–3].

A variety of numerical tests have been performed previously to illustrate the accuracy of this method. For the CE/SE Euler solver, highly accurate numerical solutions have been obtained for various flow problems involving discontinuities, such as shock waves, contact surfaces and even their interactions[4]. Moreover, applications of the same Euler solver to computational aeroacoustics (CAA) problems reveal that the accuracy of the results is comparable to that of a 4th-order compact difference scheme even though the current solver is only 2nd-order accurate, and the nonreflecting boundary condition can be implemented in a simple way without involving characteristic variables. It can be applied to subsonic, transonic, and supersonic flows in the same form without using the characteristic-based techniques. Results show that the present solver can handle both continuous and discontinuous flows very well[5–11].

In this paper, a quasi 1-D CE/SE Euler solver for a nonuniform mesh is developed and used to solve the benchmark problem in Category 1 (Internal Propagation) of the third Computational Aeroacoustics (CAA) Workshop. Among the two proposed problems, one addresses the propagation of sound waves through a transonic nozzle and another concerns shock-sound interaction in a supersonic nozzle. For problem 1, both uniform meshes with constant numerical dissipation models and nonuniform

<sup>†</sup>Aerospace Engineer, Member AIAA

<sup>‡</sup>Aerospace Engineer, Member AIAA

meshes with variable numerical dissipation models are used. Numerical results are presented and compared with the analytical solution. A good agreement is achieved by using a stretched 401 point mesh. For problem 2, 101 and 201 point uniform meshes are used and excellent agreements with the analytical solution are obtained. Further, the numerical solutions obtained by solving the linearized equations are compared with those obtained by solving the nonlinear equations for both problems.

## 2. Governing Equations and Numerical Schemes

In the following, the nonlinear quasi 1D Euler equations are described in conservative form first, which is followed by numerical schemes, numerical results and conclusions.

### 2.1 Governing Equations

The quasi 1-D Euler equations in conservative form are expressed as

$$\frac{\partial u_m}{\partial t} + \frac{\partial f_m}{\partial x} = g_m, \quad m = 1, 2, 3 \quad (1)$$

in which

$$u_1 = \rho, \quad u_2 = \rho v, \quad u_3 = p/(\gamma - 1) + \rho v^2/2 \quad (2)$$

and

$$f_1 = u_2 \quad (3)$$

$$f_2 = (\gamma - 1)u_3 + (3 - \gamma)(u_2)^2/(2u_1) \quad (4)$$

$$f_3 = \gamma u_2 u_3 / u_1 - (1/2)(\gamma - 1)(u_2)^3 / (u_1)^2 \quad (5)$$

$$g_1 = -u_2 \frac{\partial A}{\partial x} \frac{1}{A} \quad (6)$$

$$g_2 = -(u_2)^2 / u_1 \frac{\partial A}{\partial x} \frac{1}{A} \quad (7)$$

$$g_3 = -f_3 \frac{\partial A}{\partial x} \frac{1}{A} \quad (8)$$

where  $\rho, v, p$ , and  $\gamma$  are the mass density, velocity, static pressure, and constant specific heat ratio, respectively, and  $A$  is the area of a nozzle.

Let  $x_1 = x$  and  $x_2 = t$  be the coordinates of a two-dimensional Euclidean space,  $E_2$ . The integral form of Eq. (1) in space-time  $E_2$  is

$$\oint_{S(V)} \vec{h}_m \cdot d\vec{s} = \int \int_V g_m dv, \quad m = 1, 2, 3 \quad (9)$$

where (i)  $S(V)$  is the boundary of an arbitrary space-time region  $V$  in  $E_2$ ; (ii)  $\vec{h}_m = (f_m, u_m)$ ,  $m = 1, 2, 3$ , are the space-time mass, momentum, and energy flux vectors, respectively; (iii)  $d\vec{s} = d\sigma \vec{n}$  with  $d\sigma$  and

$\vec{n}$ , respectively, being the area and the outward unit normal of a surface element on  $S(V)$ ; and (iv)  $dv$  is the volume of the space-time region  $V$ . Note that (i)  $\vec{h}_m \cdot d\vec{s}$  is the space-time flux of  $\vec{h}_m$  leaving the region  $V$  through the surface element  $d\vec{s}$ ; (ii)  $\int \int_V g_m dv$  is the volume integration of the source term  $g_m$  over the space-time region  $V$ ; and (iii) all mathematical operations can be carried out as though  $E_2$  were an ordinary two-dimensional Euclidean space.

As a preliminary, let

$$f_{m,l} = \partial f_m / \partial u_l, \quad m, l = 1, 2, 3. \quad (10)$$

The Jacobian matrix  $F$ , which is formed by  $f_{m,l}$ ,  $m, l = 1, 2, 3$ , is referred to in [1].

Because  $f_m$ ,  $m = 1, 2, 3$  are homogeneous functions of degree one in  $u_1, u_2$ , and  $u_3$ , we have

$$f_m = \sum_{l=1}^3 f_{m,l} u_l. \quad (11)$$

### 2.2 The 1D Space-Time Nonuniform Mesh

Consider a nonuniform mesh shown in Fig. 1, in which the solid circles are the grid points and crosses are the solution points. Assume the spatial coordinate of the grid points be  $x_j$  with  $j = 0, 1/2, 1, 3/2, 2, 5/2$ . Generally, the grid point  $j$  is not the centroid of the line formed by grid points  $j + 1/2$  and  $j - 1/2$ . Let  $x'_j$  denote the spatial coordinate of the solution points. Define

$$x'_j = (x_{j-1/2} + x_{j+1/2})/2 \quad (12)$$

for interior mesh points, while  $x'_j = x_j$  for boundary points.

The definitions of the conservation element (CE) and solution element (SE) at a grid point  $j$  are the same as those for 1D uniform mesh in [1]. The flow marching variables are computed at the solution points, while the grid points are used to construct CEs and SEs. For later use, we define

$$\Delta x_j^- \stackrel{\text{def}}{=} x_j - x_{j-1/2} \quad (13)$$

$$\Delta x_j^+ \stackrel{\text{def}}{=} x_{j+1/2} - x_j \quad (14)$$

and

$$\Delta x_j \stackrel{\text{def}}{=} x_{j+1/2} - x_{j-1/2}. \quad (15)$$

### 2.3 The Quasi 1D Euler $a$ Scheme

For any  $(x, t) \in \text{SE}(j, n)$ ,  $u_m(x, t)$ ,  $f_m(x, t)$ , and  $\vec{h}_m(x, t)$  are approximated by  $u_m^*(x, t; j, n)$ ,

$f_m^*(x, t; j, n)$ , and  $\vec{h}_m^*(x, t; j, n)$ , respectively. They will be defined shortly. Let

$$u_m^*(x, t; j, n) \stackrel{\text{def}}{=} (u_m)_j^n + (u_{mx})_j^n (x - x'_j) + (u_{mt})_j^n (t - t^n) \quad (16)$$

where  $(u_m)_j^n$ ,  $(u_{mx})_j^n$ , and  $(u_{mt})_j^n$  are constant within  $\text{SE}(j, n)$ . Obviously, they can be considered as the numerical analogues of the values of  $u_m$ ,  $\partial u_m / \partial x$ , and  $\partial u_m / \partial t$  at  $(x'_j, t^n)$ , respectively.

Let  $(f_m)_j^n$  and  $(f_{m,l})_j^n$  denote the values of  $f_m$  and  $f_{m,l}$ , respectively, when  $u_m, m = 1, 2, 3$ , respectively, assume the values of  $(u_m)_j^n, m = 1, 2, 3$ . For any  $m = 1, 2, 3$ , let

$$(f_{mx})_j^n = \sum_{l=1}^3 (f_{m,l})_j^n (u_{lx})_j^n \quad (17)$$

and

$$(f_{mt})_j^n = \sum_{l=1}^3 (f_{m,l})_j^n (u_{lt})_j^n \quad (18)$$

Because

$$\frac{\partial f_m}{\partial t} = \sum_{l=1}^3 f_{m,l} \frac{\partial u_l}{\partial t} \quad (19)$$

and

$$\frac{\partial f_m}{\partial x} = \sum_{l=1}^3 f_{m,l} \frac{\partial u_l}{\partial x} \quad (20)$$

$(f_{mx})_j^n$  and  $(f_{mt})_j^n$  can be considered as the numerical analogues of the values of  $\partial f_m / \partial x$ , and  $\partial f_m / \partial t$  at  $(x'_j, t^n)$ , respectively. As a result, we define

$$f_m^*(x, t; j, n) \stackrel{\text{def}}{=} (f_m)_j^n + (f_{mx})_j^n (x - x'_j) + (f_{mt})_j^n (t - t^n) \quad (21)$$

Because  $\vec{h}_m = (f_m, u_m)$ , we also assume that

$$\vec{h}_m^*(x, t; j, n) = (f_m^*(x, t; j, n), u_m^*(x, t; j, n)) \quad (22)$$

Note that, by their definitions: (i)  $(f_m)_j^n$ ,  $(f_{m,l})_j^n$  are functions of  $(u_m)_j^n$ ,  $m = 1, 2, 3$ ; (ii)  $(f_{mx})_j^n$  are functions of  $(u_m)_j^n$  and  $(u_{mx})_j^n$ ,  $m = 1, 2, 3$ ; and (iii)  $(f_{mt})_j^n$  are functions of  $(u_m)_j^n$  and  $(u_{mt})_j^n$ ,  $m = 1, 2, 3$ .

Moreover, we assume that for any  $(x, t) \in \text{SE}(j, n)$ , and for  $m = 1, 2, 3$ ,

$$\frac{\partial u_m^*(x, t; j, n)}{\partial t} + \frac{\partial f_m^*(x, t; j, n)}{\partial x} = (g_m)_j^n. \quad (23)$$

Note that Eq. (23) is the numerical analogue of Eq. (1). With the aid of Eqs. (16) and (21), Eq. (23) implies that, for any  $m = 1, 2, 3$ ,

$$\begin{aligned} (u_{mt})_j^n &= -(f_{mx})_j^n + (g_m)_j^n \\ &= -\sum_{l=1}^3 [f_{m,l}^x u_{lx}]_j^n + (g_m)_j^n \end{aligned} \quad (24)$$

Since  $(g_m)_j^n$  is also a function of  $(u_m)_j^n$ ,  $m = 1, 2, 3$ , thus  $(u_{mt})_j^n$  is a function of  $(u_m)_j^n$  and  $(u_{mx})_j^n$ . From this result and the facts stated following Eq. (22), one concludes that, for each  $m = 1, 2, 3$ , there are only two independent discrete variables, i.e.,  $(u_m)_j^n$ ,  $(u_{mx})_j^n$ , associated with the mesh point  $(j, n)$ .

Further, the flux  $\vec{h}_m^*$  is conserved over  $\text{CE}_{\pm}(j, n)$ , i.e.,

$$\oint_{S(\text{CE}_{-}(j, n))} \vec{h}_m^* \cdot d\vec{s} = [(g_m)_{j-1/2}^{n-1/2} + (g_m)_j^n] \frac{\Delta t \Delta x_j^-}{4} \quad (25)$$

and

$$\oint_{S(\text{CE}_{+}(j, n))} \vec{h}_m^* \cdot d\vec{s} = [(g_m)_{j+1/2}^{n-1/2} + (g_m)_j^n] \frac{\Delta t \Delta x_j^+}{4} \quad (26)$$

where  $S(\text{CE}_{\pm}(j, n))$  denotes the boundary of  $\text{CE}_{\pm}(j, n)$ . Note that Eqs. (25) and (26) are the numerical analogues of Eq. (9).

Let  $\vec{u}_j^n$ ,  $(\vec{u}_x)_j^n$  and  $\vec{g}_j^n$ , respectively, be the  $3 \times 1$  column matrices formed by  $(u_m)_j^n$ ,  $(u_{mx})_j^n$  and  $(g_m)_j^n$ ,  $m = 1, 2, 3$ . Let  $F_j^n$  denote the  $3 \times 3$  Jacobian matrices formed by  $(f_{m,l})_j^n$ ,  $m, l = 1, 2, 3$ . Define

$$(F^+)_j^n \stackrel{\text{def}}{=} \frac{\Delta t}{4} F_j^n \quad (27)$$

$$(\vec{g}^+)_j^n \stackrel{\text{def}}{=} \frac{\Delta t}{4} \vec{g}_j^n \quad (28)$$

With the above preparations, a new set of  $3 \times 3$  matrices will be defined at each mesh point  $(j, n)$ . To simplify notation, we will strip from all  $3 \times 3$  matrices involved, their indices  $j$  and  $n$ . Define

$$\Sigma_{11}^+ \stackrel{\text{def}}{=} \Delta x_j^- I + 2F^+ \quad (29)$$

$$\Sigma_{12}^+ \stackrel{\text{def}}{=} \Delta x_j^- \left( \frac{x_{j-1/2} + x_j}{2} - x'_j \right) I + 2(F^+)^2 \quad (30)$$

$$\Sigma_{11}^- \stackrel{\text{def}}{=} \Delta x_j^- I + 2F^+ \quad (31)$$

$$\Sigma_{12}^- \stackrel{\text{def}}{=} \Delta x_j^- \left( \frac{x_{j-1/2} + x_j}{2} - x'_{j-1/2} \right) I - 2(F^+)^2 \quad (32)$$

$$\Sigma_{21}^+ \stackrel{\text{def}}{=} \Delta x_j^+ I - 2F^+ \quad (33)$$

$$\Sigma_{22}^+ \stackrel{\text{def}}{=} \Delta x_j^+ \left( \frac{x_{j+1/2} + x_j}{2} - x'_j \right) I - 2(F^+)^2 \quad (34)$$

$$\Sigma_{21}^- \stackrel{\text{def}}{=} \Delta x_j^+ I - 2F^+ \quad (35)$$

$$\Sigma_{22}^- \stackrel{\text{def}}{=} \Delta x_j^+ \left( \frac{x_{j+1/2} + x_j}{2} - x'_{j+1/2} \right) I + 2(F^+)^2 \quad (36)$$

where  $I$  is the 3x3 identity matrix.

Note that, with the aid of Eqs. (12)–(15), it can be shown that

$$\Sigma_{11}^+ + \Sigma_{21}^+ = \Delta x_j I, \quad (37)$$

$$\Sigma_{12}^+ + \Sigma_{22}^+ = 0 \quad (38)$$

Next we will show how to compute Eqs. (25) and (26). Because  $u_m^*(x, t; j, n)$  is linear in  $x$  and  $t$ , the total flux of  $\vec{h}_m^*$  leaving  $\text{CE}_\pm(j, n)$  through any one of the line segments that form its boundary is equal to the scalar product of the vector  $\vec{h}_m^*$  evaluated at the centroid of the line, and the normal vector of the line. The results of this evaluation can be combined into the matrix form

$$\begin{aligned} [\Sigma_{11}^+(\vec{u} - \vec{g}^+) + \Sigma_{12}^+\vec{u}_x]_j^n &= \\ [\Sigma_{11}^-(\vec{u} + \vec{g}^+) + \Sigma_{12}^-\vec{u}_x]_{j-1/2}^{n-1/2} \end{aligned} \quad (39)$$

and

$$\begin{aligned} [\Sigma_{21}^+(\vec{u} - \vec{g}^+) + \Sigma_{22}^+\vec{u}_x]_j^n &= \\ [\Sigma_{21}^-(\vec{u} + \vec{g}^+) + \Sigma_{22}^-\vec{u}_x]_{j+1/2}^{n-1/2}. \end{aligned} \quad (40)$$

By adding the two matrix equations and using Eqs. (37) and (38), one concludes that

$$\begin{aligned} (\vec{u} - \vec{g}^+)_j^n &= \frac{1}{\Delta x_j} \left\{ [\Sigma_{11}^-(\vec{u} + \vec{g}^+) + \Sigma_{12}^-\vec{u}_x]_{j-1/2}^{n-1/2} \right. \\ &\quad \left. [\Sigma_{21}^-(\vec{u} + \vec{g}^+) + \Sigma_{22}^-\vec{u}_x]_{j+1/2}^{n-1/2} \right\} \end{aligned} \quad (41)$$

i.e.,  $\vec{u}_j^n$  can be obtained using an iterative method, such as Newton iterative method, in terms of the marching variables at the  $(n - 1/2)$ th time level. Furthermore, it can be seen that the matrices  $(\Sigma_{rs}^+)_j^n, r, s = 1, 2$  and  $(\vec{g}^+)_j^n$ , are functions of  $\vec{u}_j^n$  only, they become known once  $\vec{u}_j^n$  is known. Thus  $(\vec{u}_x)_j^n$  can be computed using either Eq. (39) or (40).

Consider Eq. (39) for an example. Define

$$(\vec{S}_1)_j^n \stackrel{\text{def}}{=} [\Sigma_{11}^-(\vec{u} + \vec{g}^+) + \Sigma_{12}^-\vec{u}_x]_{j-1/2}^{n-1/2} - [\Sigma_{11}^+(\vec{u} - \vec{g}^+)]_j^n. \quad (42)$$

Then Eq. (39) can be rewritten as

$$[\Sigma_{12}^+\vec{u}_x]_j^n = (\vec{S}_1)_j^n. \quad (43)$$

With assumption that  $[(\Sigma_{12}^+)_j^n]^{-1}$  exists, we can have

$$(\vec{u}_x)_j^n = [(\Sigma_{12}^+)_j^n]^{-1} (\vec{S}_1)_j^n. \quad (44)$$

Note that  $(\vec{u}_x)_j^n$  can be computed in the similar way using Eq. (40). Let  $(\vec{u}_x^a)_j^n$  denote the solution. Then

the 2D CE/SE Euler  $a$  scheme is formed by Eq. (41) and

$$(\vec{u}_x)_j^n = (\vec{u}_x^a)_j^n \quad (45)$$

## 2.4 The Quasi 1D Euler $a$ - $\epsilon$ - $\alpha$ - $\beta$ Scheme

The quasi 1D CE/SE Euler  $a$ - $\epsilon$ - $\alpha$ - $\beta$  scheme for a nonuniform mesh can be derived in the same way as that for 1D CE/SE Euler  $a$ - $\epsilon$ - $\alpha$ - $\beta$  scheme for a uniform mesh.

Let

$$(u'_m)_{j\pm 1/2}^n = (u_m)_{j\pm 1/2}^{n-1/2} + (\Delta t)/2(u_{mt})_{j\pm 1/2}^{n-1/2} \quad (46)$$

and define

$$(u_{mx-}^c)_j^n \stackrel{\text{def}}{=} [(u_m)_j^n - (u'_m)_{j-1/2}^n] / \Delta x_j^- \quad (47)$$

$$(u_{mx+}^c)_j^n \stackrel{\text{def}}{=} [(u'_m)_{j+1/2}^n - (u_m)_j^n] / \Delta x_j^+ \quad (48)$$

and

$$(u_{mx}^c)_j^n \stackrel{\text{def}}{=} [(u'_m)_{j+1/2}^n - (u'_m)_{j-1/2}^n] / \Delta x_j. \quad (49)$$

Further, we can define

$$u_{mx}^w = \frac{|u_{mx-}^c|^\alpha u_{mx+}^c + |u_{mx+}^c|^\alpha u_{mx-}^c}{|u_{mx-}^c|^\alpha + |u_{mx+}^c|^\alpha} \quad (50)$$

for  $|u_{mx-}^c|^\alpha + |u_{mx+}^c|^\alpha > 0$ , otherwise  $u_{mx}^w = 0$ .

The quasi 1D CE/SE Euler  $a$ - $\epsilon$ - $\alpha$ - $\beta$  scheme is formed by Eq. (41) and

$$(\vec{u}_x)_j^n = (\vec{u}_x^a)_j^n + 2\epsilon((\vec{u}_x^c)_j^n - (\vec{u}_x^a)_j^n) + \beta((\vec{u}_x^w)_j^n - (\vec{u}_x^a)_j^n) \quad (51)$$

where  $\epsilon$ ,  $\alpha$  and  $\beta$  are parameters for controlling numerical dissipations. They can be either constants or variables. With  $\epsilon$ ,  $\alpha$  and  $\beta$  being held constant, numerical dissipation associated with the present scheme at a mesh point  $(j, n)$  tends to increase as the local Courant number  $\nu_j^n$  decreases. To compensate for this effect,  $\epsilon$  and  $\beta$  in Eq. (51) may be replaced by  $\epsilon(\nu_j^n)$  and  $\beta(\nu_j^n)$  which are expressed as

$$\begin{aligned} \epsilon(\nu_j^n) &= 0.5 \nu_j^n \exp(1 - \nu_j^n) \quad \text{and} \\ \beta(\nu_j^n) &= \sqrt{\nu_j^n}, \quad 0 \leq \nu_j^n \leq 1. \end{aligned} \quad (52)$$

Note that  $\epsilon(\nu_j^n)$  and  $\beta(\nu_j^n)$ , are monotonically increasing function of  $\nu_j^n$  with  $\epsilon(0) = 0$  and  $\beta(0) = 0$ . A 1D CE/SE Euler solver with  $\epsilon(\nu_j^n)$  and  $\beta(\nu_j^n)$  in Eq. (52) was used in [1] to obtain accurate shock tube solutions with the maximal Courant number in each numerical simulation ranging from 0.88 to 0.022.

Similarly, the quasi 1D CE/SE Euler solver is second-order accurate in both space and time. The

stability condition is the Courant number less than unity.

### 3. Numerical Results

For the two problems solved in the following, the CE/SE quasi 1D Euler solver described previously for the nonlinear equations is used to compute the steady-state solution of the nozzle flowfield. For the simulation of acoustic wave propagation, both the linear and nonlinear quasi 1D Euler solvers are used under the same computational conditions. The linear solver is constructed for the linearized quasi 1D Euler equations in conservative form. It has the identical formulation as the nonlinear solver except the time-marching variables are different. The details of the linear solver will be described in a separate paper. Both the linear and nonlinear numerical solutions are presented. Numerical solutions of the acoustic wave plotted in all figures are non-dimensionalized by its amplitude  $\varepsilon$ . In the computations using a uniform mesh, the constant numerical dissipation model with  $\epsilon = 0.2$ ,  $\alpha = 0$ , and  $\beta = 1$  is used for both problems.

#### 3.1. Propagation of Sound Waves through a Transonic Nozzle

The first problem addresses propagation of sound waves in a transonic nozzle, in which the local Mach number of flow near the throat may be close to sonic. The computation of sound propagating through such regions presents a challenging problem. The area of the nozzle is

$$A(x) = \begin{cases} 0.536572 - 0.198086 \exp\left(-(\ln 2)\left(\frac{x}{0.6}\right)^2\right), & x > 0 \\ 1.0 - 0.661514 \exp\left(-(\ln 2)\left(\frac{x}{0.6}\right)^2\right), & x < 0. \end{cases} \quad (53)$$

In the uniform region downstream of the throat, the diameter of the nozzle is  $D$  and the main flow is uniform with Mach number,  $M_\infty$ , of 0.4, speed of sound,  $a_\infty$ , and static density,  $\rho_\infty$ . Flow variables are non-dimensionalized by using  $a_\infty$  as the velocity scale,  $D$  as the length scale,  $D/a_\infty$  as the time scale,  $\rho_\infty$  as the density scale, and  $\rho_\infty a_\infty^2$  as the pressure scale. Thus the mean flow in the uniform region downstream of the throat is

$$\rho = 1, \quad v = 0.4, \quad p = 1/1.4. \quad (54)$$

The acoustic wave, with angular frequency  $\omega = 0.6\pi$ , is described as

$$\rho' = p' = \varepsilon \cos \left[ \omega \left( \frac{x}{1 - M_\infty} + t \right) \right],$$

$$v' = -\varepsilon \cos \left[ \omega \left( \frac{x}{1 - M_\infty} + t \right) \right] \quad (55)$$

where  $\varepsilon = 10^{-4}$ . It is generated downstream and propagates upstream through the narrow passage of the nozzle throat. The computational domain is  $-10 \leq x \leq 10$ . It is recommended that computations use no more than 400 mesh intervals.

As the first step, the steady-state solution of the nozzle flow is computed. The initial conditions are specified using flow properties in the uniform downstream region. For imposing the boundary conditions, the back pressure ( $p_{back} = 1/1.4$ ) is specified at the outlet, and the total pressure and total density are specified at the inlet. The other needed information at both the inlet and outlet are obtained using extrapolation from their neighboring mesh points. The steady-state solution obtained using a 401 point uniform mesh with  $CFL = 0.847$  is shown in Fig. 2 in comparison with the exact solution represented by solid lines. It can be seen that flow properties are uniform in most region of the nozzle, but change dramatically near the nozzle throat.

After the steady-state nozzle flowfield is available, the acoustic wave propagation can be simulated using the same nonlinear Euler solver. The initial conditions are specified using the steady-state solution of nozzle flowfield. The boundary condition is different from that used for computing the steady-state solution. At the outlet, the time-marching variables are specified as

$$(u_1)_j^n = \rho + \rho' \quad (56)$$

$$(u_2)_j^n = (\rho + \rho')(v + v') \quad (57)$$

$$(u_3)_j^n = \frac{p + p'}{\gamma - 1} + \frac{1}{2}(\rho + \rho')(v + v')^2. \quad (58)$$

At the inlet, the non-reflecting boundary condition is enforced by setting

$$(u_m)_j^{n+1/2} = (u_m)_{j+1/2}^n, \quad (u_{mx})_j^{n+1/2} = 0 \quad (59)$$

where  $m = 1, 2, 3$ .

Different mesh sizes are tested in the current computation. First, uniform meshes with  $\Delta x = 0.05$  and  $0.025$  in the computational domain of  $-10 \leq x \leq 10$  are used. Numerical solutions of the acoustic pressure  $p'$  at  $t = 20T$  are shown in Figs. 3 and 4, respectively and compared with the analytical solution. It can be seen that the peak values near the throat and wave pattern upstream of the throat can not be captured correctly using a 401 point uniform mesh, while a greatly improved result is produced using an 801 point uniform mesh. The amplitude of the acoustic wave upstream of the throat is lower than

that given by the analytical solution. Further, the corresponding solutions obtained with  $\Delta x = 0.0125$  in the computational domain of  $-5 \leq x \leq 5$  are shown in Fig. 5. Although the peak values are still not the same as the analytical solution, the profiles of the  $p'$  both upstream and downstream of the throat agree very well with the analytical solution.

In order to reduce the number of grid points, a 401 point nonuniform mesh that cluster near the throat is used. The ratio of the largest to smallest mesh interval is around 10 with  $\Delta x_{min} = 0.0047$ . The variable  $\epsilon_j^n$  and  $\beta_j^n$  described in Eq. (52), and constant  $\alpha = 0$  are used in the computation. The obtained acoustic pressure at  $t = 20T$  with  $CFL = 0.9084$  is shown in Fig. 6 which is nearly similar to that obtained using an 801 point uniform mesh in the domain of  $-10 \leq x \leq 10$ . Further improvement can be made in the future by reducing the numerical dissipations or using a more stretched mesh. Its convergence to the time-period solution is shown in Fig. 7. Under the same computational conditions and mesh, the corresponding solution obtained using  $\varepsilon = 10^{-3}$  is plotted in Fig. 8 showing skewness upstream of the throat. It can be concluded that the amplitude of the acoustic wave should be small enough to avoid the nonlinearity when a nonlinear scheme is used to obtain the linear solution. In the present computation using a nonlinear solver, the steady-state solutions converge to  $10^{-7}$ , and  $\varepsilon = 10^{-4}$  is used.

For the linear solver, the amplitude of the acoustic wave is set to 1 and the steady-state solution obtained by using the nonlinear solver is used in the computation. All the three uniform meshes used for the nonlinear solver described above are tested with the linear solver. The linear solutions are very similar to the nonlinear solutions. The solution obtained using an 801 point uniform mesh in the domain of  $-10 \leq x \leq 10$  is shown in Fig. 9 as an example. The nonlinear solution is slightly better than the linear solution under the same computational conditions.

### 3.2 Shock-Sound Interaction

In this problem, the same nozzle geometry from the previous problem is used, but here there is a supersonic shock downstream of the throat. All quantities are non-dimensionalized using the upstream values. The Mach number at the inlet,  $M_\infty$ , is 0.2006533 and the back pressure,  $p_{back}$ , is 0.6071752. Following the same steps described in the first problem, the steady-state nozzle flowfield is computed and used as the initial condition for the sound-shock interaction simulation. The acoustic wave is described as

$$\rho' = p' = v' = \varepsilon \sin \left[ \omega \left( \frac{x}{1 + M_\infty} + t \right) \right] \quad (60)$$

where  $\varepsilon$  and  $\omega$  have the same values as that in the first problem. At the inlet, the time-marching variables are specified using Eqs. (56)–(58), while at the outlet, for  $m = 1, 2, 3$ ,

$$(u_m)_j^{n+1/2} = (u_m)_{j-1/2}^n, \quad (u_{mx})_j^{n+1/2} = 0 \quad (61)$$

are used as the non-reflecting boundary conditions.

Uniform meshes with 101 and 201 grid points are used for this problem. The steady-state solution obtained using a 101 point uniform mesh is shown in Fig. 10 and compared with the analytical solution represented by solid lines. Numerical solutions of the acoustic wave obtained using 101 and 201 point uniform meshes are shown in Fig. 11, in which only the analytical solution of  $p'$  is plotted for a comparison. The analytical solutions of the density and velocity are not available. It can be seen that the solution obtained on a 101 point uniform mesh is very close to the analytical solution and that obtained on a 201 point uniform mesh appears to graphically match the analytical solution. A very solid convergence to the time-period solution is demonstrated in Fig. 12 for the coarse mesh. Further, the acoustic pressure at the outlet in one time period is plotted in Fig. 13 along with the analytical solution showing an excellent agreement. The linear solution is almost identical to the nonlinear solution which is shown in Fig. 14 for a 101 point uniform mesh.

## 4. Conclusions

The quasi 1-D CE/SE Euler solver for a nonuniform mesh is developed and applied to simulate the propagation of sound waves and shock-sound interaction in a nozzle. For problem 1, a satisfactory numerical result is obtained using a nonuniform mesh with 401 grid points. For problem 2, an excellent agreement between the numerical results obtained on a 101 point uniform mesh and the analytical solution is achieved. It is demonstrated that the CE/SE method is capable of solving aeroacoustic problems with/without shock waves in a simple way. No special techniques are used for shock waves, and acoustics waves and shock waves can be captured concurrently within the computational domain.

## Acknowledgments

This work was supported by NASA Glenn Research Center through Contract NAS3-97186. The first author would like thank Dr. Ray Hixon for providing the analytical solutions of both problems.

13. ABSTRACT (Maximum 200 words)  The benchmark problems in Category 1 (Internal Propagation) of the third Computational Aeroacoustics (CAA) Workshop sponsored by NASA Glenn Research Center are solved using the space-time conservation element and solution element (CE/SE) method. The first problem addresses the propagation of sound waves through a nearly choked transonic nozzle. The second one concerns shock-sound interaction in a supersonic nozzle. A quasi one-dimension CE/SE Euler solver for a nonuniform mesh is developed and employed to solve both problems. Numerical solutions are compared with the analytical solution for both problems. It is demonstrated that the CE/SE method is capable of solving aeroacoustic problems with/without shock waves in a simple way. Furthermore, the simple nonreflecting boundary condition used in the CE/SE method which is not based on the characteristic theory works very well.
